1 DATA CLEANING

In the data cleaning process, I initally encountered a lot of missing values. However, upon further analysis I found out that it was because the survey respondent didnt select the given option from multiple choice question. The following are the steps I took to clean the data:

- 1. Removing naan records (entire rows) from columents that has less than 10% naan values because the feature column already has rich amount of data.
- 2. Removing 'Other Text' column as it has no meaning in the dataset.
- 3. Identifying features that has more than 70% naan values and removing them.

- 4. Removing few identified features from the gender and qualification question as it had very low percentage of records (based on data exploration).
- 5. Cleaning target feature by removing naan records and answers that very low percentage of records selected.
- 6. All the categorical data with binary text answers are label encoded (0 or 1).
- 7. All the categorical data with multiple answers are one hot encoded.
- 8. All the categorical data in the survey that required text answers (which were eventually converted to integers in csv) are convered to either 1 or 0. If the surveyer didnt type anything then the csv file shows -1 which is converted to 0. If the surveyer typed anything then the csv file shows a positive number based on the numer of characters, this is coverted to 1 which shows the user typed something.
- 9. All the remaining features with integer data are normalized and the time to complete feature is dropped as it does not add any value.

After the cleaning and endociding process, I eneded up with clean dataset that had 11,390 records and 64 features.

```
#Importing the file
    response=pd.read_csv("multiple_choice_response.csv", encoding = "ISO-8859-1")
    #Deleting column header and replacing it with row 1. Also changing column index
    response.columns=response.iloc[0]
    response=response.drop(response.index[0])
    response=response.reset_index(drop=True)
                             ##
                                    DATA CLEANING PART I
    ###Removing Naan records from column that has less than 10% naan values###
    ###Why: Beacause features already has a rich source of data###
    #Percentage of responses required for keeping the rows
    percentage_required=10
    #Determining cutoff number:
    total_record=response.shape[0] #total number of records
    cutoff_num=round(total_record*(percentage_required/100))
    #Identifying features that has less than 10% Naan values
    null_records_remove_1=response.isnull().sum(axis=0)
    null_records_remove_1=pd.Series(null_records_remove_1).where(lambda x :_ u
     →x<cutoff num).dropna()</pre>
```

```
null_records_remove_1=pd.Series(null_records_remove_1).where(lambda_x : x!=0).
 →dropna()
rows_remove=null_records_remove_1.index.tolist()
#Removing identifying rows:
response 1=response.dropna(axis=0, subset=rows remove)
                           ## DATA CLEANING PART II ##

Total number of features: 664

2 EXPLORATORY DATA ANALYSIS

Four different graphical figures are created in order to understand the trend in the data. The following are the figures and the reasoning behind using it.

- 1. Number of records per salary range This figure is very important as it helps us visualize the distribution of records per target variable. Upon anlysis, I found that the distribution is severely imbalanced as there are more than 2900 records for "0-10,000" range and less than 50 records for 500,000+. Futheremore, it can be seen that the records become exponentially less once the salary range crosses 150,000. That is why I grouped together the salary range from 150,000 to 500,000+. This would balance the dataset and help the model predcict accurate results. Another figure with the new distribution of records per salary range is also shown.
- 2. Number of records per country This figure shows the number of records per country. In this case, I could not find any trend from this graph, other than the fact that US has too many records as compared to other countries. Since the requirement for each salary range could be different for different countries, I did not many any changes to the dataset.
- 3. Number of records per gender This figure helped me determine that there was a very less percentage of records that did not claim any gender. As a result, those records were removed because they would not add any value. This helped me do label encoding on gender feature as there are only two responses (male and female). The updated distribution of gender ratio per record was plotted.
- 4. Degree distribution per records This figure showed the distribution of degrees per records. Upon analysis I found that there were records that didnt prefer to answer. Those records

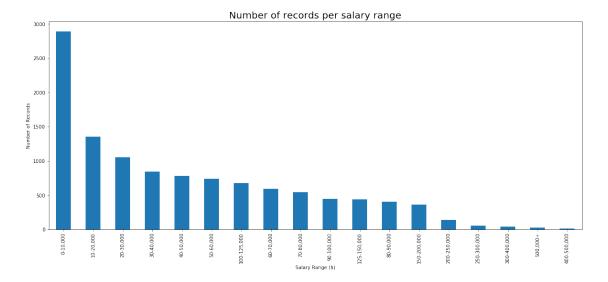

were removed in the data cleaning process.

These data visualziation methods helped me understand the trend in the dataset and also clean it in more depth (after I was able to understand the relationships). Also, a correlation heatmap was plotted but since I have too many features, it became difficult to go through each correlations. As a result, I decided to use correlation in the feature selection Part.

```
[3]: #Bar plot to visualize the distribution of cleaned data
fig_1=clean_data['What is your current yearly compensation (approximate $USD)?

→_y'].value_counts().plot(kind='bar',figsize=(20,8))
plt.xlabel('Salary Range ($)',fontsize=10)
plt.ylabel('Number of Records',fontsize=10)
plt.title('Number of records per salary range',fontsize=20)
```

[3]: Text(0.5, 1.0, 'Number of records per salary range')

As there seems to uneven distribution of data, it can be seen that the records become exponentially less once the salary range crosses \$150,000. That is why I grouped together the salary range from 200,000 to 500,000+. This would help me keep majority of the samples in the rare class (salary ranges with less records) while randomly selecting an equal number of samples from the abundant class. A balanced new dataset can be retrieved for further modelling. This would yield accurate results.

```
[4]: #Grouping salary buckets of 200,000 to 500,000

clean_data['What is your current yearly compensation (approximate $USD)?

→_y']=clean_data['What is your current yearly compensation (approximate $USD)?

→_y'].replace({'100-125,000':'150,000+','125-150,000':

→'150,000+','150-200,000':'150,000+','200-250,000':'150,000+', '250-300,000':

→'150,000+', '300-400,000':'150,000+', '400-500,000':'150,000+', '500,000+':

→'150,000+' })
```

```
#Plot representing new distribution of data:

#Bar plot to visualize the distribution of cleaned data

fig_2=clean_data['What is your current yearly compensation (approximate $USD)?

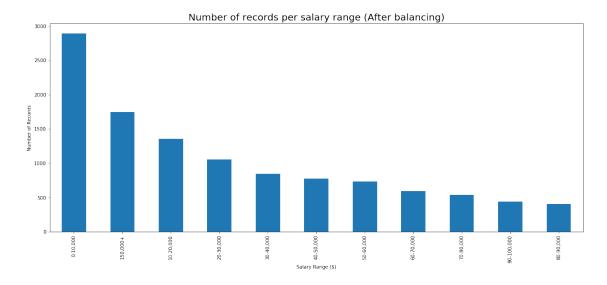

→_y'].value_counts().plot(kind='bar',figsize=(20,8))

plt.xlabel('Salary Range ($)',fontsize=10)

plt.ylabel('Number of Records',fontsize=10)

plt.title('Number of records per salary range (After balancing)',fontsize=20)
```

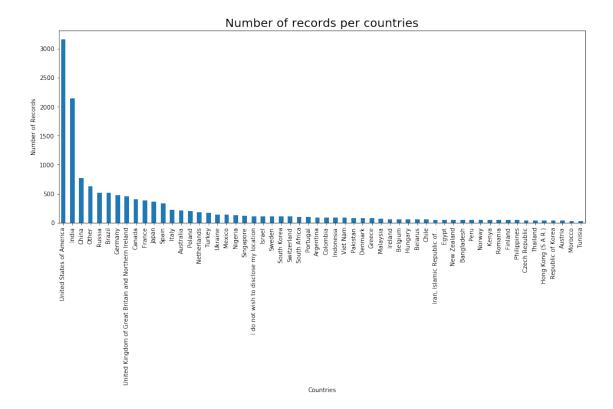

[4]: Text(0.5, 1.0, 'Number of records per salary range (After balancing)')

```
[5]: #Bar plot to visualize the distribution of cleaned data
fig_1=response_5['In which country do you currently reside?'].value_counts().

→plot(kind='bar',figsize=(16,6))
plt.xlabel('Countries',fontsize=10)
plt.ylabel('Number of Records',fontsize=10)
plt.title('Number of records per countries',fontsize=20)
```

[5]: Text(0.5, 1.0, 'Number of records per countries')

From the above graph, it can be seen that United States of America has a lot of records in comparison to other countures. The distribution is severely uneven but I will not use any technique as it does not concern the target variable (salary).

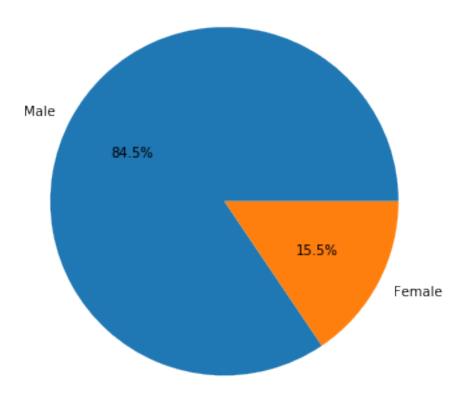

Next, I will try to see the gender distribution distribution per records. I initially found that 0.8% of the records were either "Prefer to self-describe" and "Prefer not to say". As a results these records were initially removed in Data Cleaning Part II. Resulting pie chart can be see below. The removed records would not add any value and their removal would yield better results for our model.

```
[6]: #Bar plot to visualize the distribution of cleaned data
fig_1=response_5['What is your gender? - Selected Choice'].value_counts().

→plot(kind='pie',autopct='%1.1f%%',figsize=(16,6))
plt.xlabel('Gender distribution per records',fontsize=10)
plt.title('Number of records per gender',fontsize=20)
plt.ylabel('',fontsize=10)
```

[6]: Text(0, 0.5, '')

Number of records per gender

Gender distribution per records

Next, I will try to see the degree distribution per records. I initially found that a very low percentage of records were "I prefer not to answer". As a result, these records were removed in Data Cleaning Part II because they would not add any value to our model. Resulting bar chart can be seen below.

```
[7]: #Bar plot to visualize the distribution of cleaned data

fig_1=response_5['What is the highest level of formal education that you have_

→attained or plan to attain within the next 2 years?'].value_counts().

→plot(kind='bar',figsize=(16,6))

plt.xlabel('Degree Distribution',fontsize=10)

plt.ylabel('Number of Records',fontsize=10)

plt.title('Degree distribution per records',fontsize=20)
```

[7]: Text(0.5, 1.0, 'Degree distribution per records')

font.set_text(s, 0, flags=flags)

In order to visualize the importance of each feature, a correlation plot was plotted as a heat map. The correlation plot is too big as there are too many features. That is why I commented it out as it will become very slow if correlation plot is plotted. The correlation plot will be used in the feature selection section.

```
[8]: #Correlation matrix
#corr=clean_data.corr().abs()
```

```
#Creating correleation matrix
#corr.style.background_gradient(cmap='coolwarm',low=0).set_precision(2)
```

3 FEATURE SELECTION

Feature engineering is a very useful tool in machine learning. It is a process of extracting the most relevant features from the dataset and then applying machine learning algorithms for the better performance of the model. A large number of irrelevant features increases the training time exponentially and will also increase the risk of overfitting.

I did feature engineering in multiple steps. Initially, a correlation matrix was plotted and then features with correlation coefficient of more than 70% was identified. After that, one of them was removed (from the pair). Removing features with high colinearity will improve the performance of our model as keeping both would be counter-productive.

After reducing the number of features bases on high colinearity, I used Chi Square test for feature extraction. Chi-square test is used for categorical features in a dataset. In my case, the target is categorical (I kept it as it is). We calculate Chi-square between each feature and the target and select the desired number of features with best Chi-square scores. It determines if the association between two categorical variables of the sample would reflect their real association in the population.

After identifying desired number of featurs, Principal Component Analysis was used to reduce the dimensionality of data. It would help in proving a better estimate. I would like to clarify that I used Chi square test to first identify important features from the dataset and then I used PCA to reduce the dimensionality of the dataset without losing any information.

```
[9]: #Correlation matrix
     #Removing features with high colinearity using correlection matrix
     corr=clean_data.corr().abs()
     #Creating correleation matrix
     corr.style.background gradient(cmap='coolwarm',low=0).set precision(2)
     #Select upper triangle of correleation matrix
     upper = corr.where(np.triu(np.ones(corr.shape), k=1).astype(np.bool))
     #Finding index of feature columns with correlation greater than 0.70
     to drop = [column for column in upper.columns if any(upper[column] > 0.7)]
     #Dropping identified features
     clean_data_v1=clean_data.drop(clean_data[to_drop], axis=1)
     #Chi-Squared for Feature selection
     # Create features and target
     target_sal=['What is your current yearly compensation (approximate $USD)?_y']
     y=clean data v1.filter(target sal)
     x=clean data v1.drop(target sal,axis=1)
```

Total number of features after dropping features with high colinearity: 648

Total number of features after using Chi Square test 10

Total number of features after Principal Component Analysis 5

4 MODEL IMPLEMENTATION

Logistic Regression model is used as specified in the problem set. As there in an uneven distribution of samples, class_weight="balanced" is used as it basically means replicating the smaller class until you have as many samples as the larger one. Regularization is also used as it is a way to avoid overfitting by penalizing high-valued regression coefficients. It reduces parameters and simplifies the model. Regularization is necessary because least squares regression methods, where the residual sum of squares is minimized, can be unstable. This is especially true if there is multicollinearity in the model. In this case, Lasso regression is used. L1 regularization adds an L1 penalty equal to the absolute value of the magnitude of coefficients. In other words, it limits the size of the coefficients. All the features are normalized in the preprocessing part, therefore; I do not need to scale/normalize anything here.

Lastly, 10 fold stratified cross validation is used and precision scores across all the folds are printed along with average accuracy and variance of accurancy.

```
logmodel.fit(X_train, y_train)
#Cross validation (10 fold)
skf = StratifiedKFold(n_splits=10)
accuracy = cross_val_score(logmodel, x, y, cv=skf, scoring='accuracy')_u
 →#Accuracy across folds
avg_accuracy= cross_val_score(logmodel, x, y, cv=skf,scoring='accuracy').mean()__
 →#Average accuracy for folds
avg_variance= cross_val_score(logmodel, x, y, cv=skf,scoring='accuracy').var() u
 →#Average variance of accuracy
avg_recall = cross_val_score(logmodel, x, y, cv=skf, scoring='recall_macro',).
 →mean() #Average recall for folds
avg_precision = cross_val_score(logmodel, x, y, cv=skf,_
 →scoring='precision_macro').mean() #Average precision for folds
avg_f1 = cross_val_score(logmodel, x, y, cv=skf, scoring='f1_macro').mean()_u
 →#Average f1 for folds
#Predictions (Probability of belonging to each salary bucket is printed)
Pred_cross_val = cross_val_predict(logmodel, x, y, cv=skf)
print ('\nResults:')
print ('\nAccuracy across each fold: ', accuracy)
print ('\nAverage accuracy across 10 folds:', round(avg_accuracy,2))
print ('\nVariance of accuracy across 10 folds: ', round(avg variance,5))
print ('\nAverage recall across 10 folds: ', round(avg_recall,2))
print ('\nAverage precision across 10 folds: ', round(avg_precision,2))
print ('\nAverage F1 score across 10 folds: ', round(avg_f1,2))
print ('\nProbability of belonging to each salary bucket:')
print(classification_report(y,Pred_cross_val))

```

The best model is when the value of hyperparameter (C) is 1. Below, learning curve using this parameter is plotted in order to show bias-variance. Both the training and validation curves are close to each other and converges at low complexity. This shows that the model is working well and is not underfitting or overfitting.

```

<Figure size 432x288 with 0 Axes>

5 MODEL TUNING

In order to tune the model, a grid search is used to determine the optimal model selected. The accuracy metrics selected are precision and recall. I would want to correctly identify the salary range based on the skillset of the candidate. Also, the grid search is commented out and the results are printed below. The hyperparameters that are being tuned are C, penalty and class_weight.

```
[13]: # Grid search cross validation

#from sklearn.model_selection import GridSearchCV

#from sklearn.linear_model import LogisticRegression

#grid={"C":np.logspace(-10,10), "penalty":["l1","l2"], "class_weight":[None, "one, "
```

```
#logmodel = LogisticRegression(C=50, penalty='l1',class_weight = "\"balanced",solver='liblinear',multi_class='ovr'
#logreg_cv.fit(X_train,y_train)

#print("Tuned hpyerparameters :(best parameters) ",logreg_cv.best_params_)
#print("Best Accuracy :",logreg_cv.best_score_)
```

Based on grid search, the following are the results: Tuned hpyerparameters :(best parameters) {'C': 0.03727593720314938, 'class_weight': 'balanced', 'penalty': 'l1'} Best Accuracy : 0.8594004766085539

Using tuned hyper-parameters, the following are the crossvalidated scores of the metrics chosen to select the model.

```

6 Testing & Discussion

The optimal model that have been determined from the previous sections will be used to make classification on the test set. The accuracy of the model on both the train and test set will is shown as well along with the learning curve.

```
[15]: #Accuracy on training set

print ('Accuracy on training set: (To see if the model is overfitting or

→underfitting):')

train_pred = logmodel.predict(X_train)

print(classification_report(y_train,train_pred))

print('\nSince the accuracy of the training set is pretty close to the accuracy

→of the testing set, it can be safely concluded that the model is not

→underfitting or overfitting.')
```

Accuracy on training set: (To see if the model is overfitting or underfitting): precision recall f1-score support

| 0-10,000 | 0.91 | 0.99 | 0.95 | 2037 |
|-----------|------|------|------|------|
| 10-20,000 | 0.78 | 0.74 | 0.76 | 957 |
| 150,000+ | 0.77 | 0.71 | 0.74 | 1218 |
| 20-30,000 | 0.86 | 0.83 | 0.85 | 727 |
| 30-40,000 | 0.85 | 0.80 | 0.83 | 618 |
| 40-50,000 | 0.83 | 0.81 | 0.82 | 517 |
| 50-60,000 | 0.84 | 0.84 | 0.84 | 487 |

| 60-70 | ,000 | 0.80 | 0.61 | 0.69 | 418 |
|----------|------|------|------|------|------|
| 70-80 | ,000 | 0.77 | 0.98 | 0.86 | 386 |
| 80-90 | ,000 | 1.00 | 1.00 | 1.00 | 291 |
| 90-100 | ,000 | 1.00 | 1.00 | 1.00 | 317 |
| | | | | | |
| micro | avg | 0.85 | 0.85 | 0.85 | 7973 |
| macro | avg | 0.85 | 0.85 | 0.85 | 7973 |
| weighted | avg | 0.85 | 0.85 | 0.85 | 7973 |

Since the accuracy of the training set is pretty close to the accuracy of the testing set, it can be safely concluded that the model is not underfitting or overfitting.

<Figure size 432x288 with 0 Axes>

After completing all the steps, I can confidently conclude that the overall fit of the model is good. It is not overfitting or underfitting as can be seen from the learning curve above. The model also converges to an acceptable accuracy score at low complexity. Initially, I was getting accruacy of 70 percent. After tuning the hyperparameters, I am getting an accuracy of 85 percent with the help of grid search.

Furthermore, the accuracy of the model could be increased by balancing the dataset using undersampling techniques such as SMOTE or ADASYN. Synthetic mintority oversampling technique or Adaptive synthetic sampling method would create more samples for the minority class by taking existing information from the exisitng samples. A balanced dataset would provide higher unbiased accuracy. Lastly, the there is a lot of noise present in the dataset that should be removed. Refining the dataset would increase accuracy. Examples of noise would include records of students having a salary of more than 250,000+. Those records should be moved. Also, I personally feel that the dataset is misleading. Salary range is geographic as someone with the same skillset could be earning a lot more in Western countries than Eastern countries. As a result, the model would get confused and give inaccurate results. That is why the model should be implemented indivudally for a specific geographic location in order to get accurate estimates.
